ABSTRACT

This research examines the stochastic resonant nonlinear Schrödinger equation (NLSE) with cubic-quintic-septic nonlocal nonlinearity in the Itô framework, incorporating spatio-temporal dispersion (STD), inter-modal dispersion (IMD), resonant nonlinearities, and multiplicative white noise. Using Kudryashov's method and the P^6 -model expansion approach, novel families of bright, dark, singular, Jacobi-elliptic, and periodic stochastic solitons are derived, with exact constraint conditions ensuring physical validity. Numerical simulations reveal noise-induced amplitude modulation, phase jitter, rogue-wave-like spikes, and stochastic resonance phenomena that transition periodic backgrounds into emergent soliton structures. These findings demonstrate multiplicative noise's dual role in destabilizing conventional solitons while generating resonance-enhanced coherent waveforms, filling the gap in unified models combining higher-order nonlinearities, nonlocality, and stochasticity. The numerical results were obtained using the split-step Fourier method to validate the analytical findings. The results advance soliton theory for realistic optical fibers, photonic lattices, metamaterials, and plasma systems, enabling noise-robust signal transmission and nonlinear wave control.

1. Introduction

The nonlinear Schrödinger equation (NLSE) serves as a fundamental framework in mathematical physics, characterizing the dynamics of slowly varying wave envelopes within nonlinear and dispersive media. It serves a crucial function in various physical systems, including nonlinear optics, plasma waves, Bose–Einstein condensates, and fluid dynamics [23,24]. The interplay between dispersion and nonlinear self-action in the nonlinear Schrödinger equation results in solitons, which are localized and stable wave packets that preserve their shape while propagating. The implications of these solitons are substantial in the fields of optical communication, photonic device engineering, and nonlinear wave theory [26].

Various generalizations of the NLSE have been proposed to tackle the complexities inherent in real-world systems. Models incorporating

cubic–quintic and higher-order refractive index laws have been developed to account for saturation, multi-photon absorption, and the interplay of focusing and defocusing effects [25,26]. Nonlocal nonlinearities have garnered interest due to their ability to represent long-range interactions and provide stability to waveforms, preventing collapse [11]. These extensions enhance the applicability of the NLSE to realistic optical fibers, photonic lattices, metamaterials, and plasma environments.

The fractional form of the nonlinear Schrödinger equation (NLSE) is investigated because many physical systems exhibit memory effects, anomalous dispersion, and long-range interactions that cannot be adequately described by the classical integer-order NLSE. The conformable fractional derivative offers a mathematically consistent tool to incorporate these effects while retaining useful analytical properties such as linearity and the classical chain rule

A significant element frequently observed in physical systems is stochasticity. Noise sources such as thermal fluctuations, spontaneous emission, and environmental disturbances inherently influence nonlinear media. The integration of randomness into governing models is typically accomplished via stochastic extensions of the NLSE, frequently expressed in the Itô sense with multiplicative white noise [1,2,4]. Recent studies have shown that noise, often viewed as solely detrimental, can play a constructive role by inducing stochastic resonance, enhancing weak signals, and stabilizing solitons [3,6,7,16,27].

While prior stochastic NLSE models have explored cubic-quintic nonlinearities or nonlocal effects separately [1–7], the proposed model in Eq. (1) uniquely unifies cubic, quintic, and septic nonlocal nonlinearities with resonant terms, intermodal dispersion, and multiplicative noise in the Itô framework. Unlike existing studies that typically focus on lower-order nonlinearities or local responses, this work systematically incorporates higher-order refractive index saturation, nonlocality, and stochastic forcing—features that coexist in realistic optical and plasma systems. This comprehensive approach enables the derivation of new soliton families and reveals noise-driven phenomena not captured in earlier stochastic or deterministic models. Recently, considerable attention has been devoted to constructing analytical and semi-analytical solutions of nonlinear evolution equations due to their relevance in optical communication, fluid dynamics, and plasma modeling. For instance, the first-integral method has been employed to derive closed-form solutions for the Wu–Zhang system with conformable time-fractional derivatives [49], while modified mapping-type techniques have been utilized to obtain diverse exact solutions of the Davey–Stewartson model [50]. Moreover, recent studies have examined the dynamics of multidimensional optical solitons in extended conformable Kudryashov frameworks with generalized nonlinear responses [51] demonstrating the effectiveness of advanced analytical schemes. These developments provide strong motivation to further explore stochastic influences on nonlinear wave structures, as pursued in the present work.

Numerous studies have investigated stochastic soliton dynamics in various models, including the stochastic Ginzburg–Landau equation [6], the Hirota–Maccari system [7], the Konno–Oono model [8], and stochastic adaptations of the Gerdjikov–Ivanov equation [13,16]. Nevertheless, the majority of these studies are confined to lower-order nonlinearities or overlook nonlocal effects. The combined effects of cubic–quintic–septic nonlinearities, nonlocality, resonant terms, and multiplicative noise within a unified NLSE framework have yet to be systematically examined. This indicates a notable disparity, as such effects inherently coexist in realistic photonic and plasma systems.

This represents a critical research gap: no prior study unifies cubic–quintic–septic nonlocal nonlinearities, resonant terms, STD, IMD, and multiplicative Itô noise within a single NLSE framework—effects that coexist in high-power optical fibers and metamaterials [1–29,39–41].

Recent studies continue to expand the applicability and solution families of the NLSE. For instance, research has explored optical solitons in metamaterials with generalized non-local nonlinearity, highlighting novel solution behaviors in advanced media [30]. Further investigations have yielded exact solutions for the conformable fractional NLSE with Kerr and power laws, bridging fractional calculus with nonlinear optics [31]. The dynamics have also been extended to $(3+1)$ -dimensional frameworks, uncovering resonant dissipative solitons that enrich the understanding of higher-dimensional wave propagation [32]. Additionally, studies on the stochastic fractional NLSE have provided insights into soliton dynamics under the combined influence of fractional derivatives and noise [33]. The analysis of cubic–quartic solitons in birefringent fibers without four-wave mixing has demonstrated the role of higher-order dispersion in sustaining stable pulses [34], while other works have focused on optical solitons with complex Ginzburg–Landau-type equations incorporating nonlinear chromatic dispersion [35]. These contributions underscore the ongoing evolution of NLSE models to capture more complex physical effects and solution structures.

The analytical approaches employed in this study, namely Kudryashov’s algorithm and the P^6 -model expansion method, offer distinct advantages for tackling such a complex system. Kudryashov’s method is renowned for its systematic and rigorous algebraic procedure, which efficiently extracts a wide spectrum of soliton solutions—including bright, dark, and singular types—by leveraging a specially chosen auxiliary equation [36–38]. Its key strength lies in its ability to handle high-order nonlinearities without introducing unnecessary complexity. Complementarily, the P^6 -model expansion method is exceptionally powerful for deriving a broader class of solutions, particularly Jacobi elliptic and periodic solutions, which can degenerate into various soliton forms under specific parameter limits. The synergy of these two methods ensures a more comprehensive and robust exploration of the model’s solution space than either could achieve alone.

The incorporation of a stochastic process, specifically multiplicative noise within the Itô framework, is of profound significance as it transitions the model from an idealized, deterministic system to one that reflects the inherent randomness of real physical environments. In practical settings—be it an optical fiber subject to thermal fluctuations and spontaneous emission, a plasma with turbulent density variations, or a Bose–Einstein condensate interacting with a thermal cloud—noise is an inescapable factor. By accounting for this stochasticity, the model captures crucial phenomena such as amplitude jitter, phase diffusion, and stochastic resonance, where noise can paradoxically enhance signal transmission or stabilize wave structures. This approach reveals that noise is not merely a disruptive nuisance but a fundamental physical parameter that can dictate dynamical transitions, induce the formation of rare events like rogue waves, and ultimately govern the stability and longevity of solitons. Therefore, a stochastic analysis is indispensable for predicting the robust performance of nonlinear waves in technological applications and for achieving a more complete, physically realistic understanding of wave propagation in complex media.

Here we fill this void with Eq. (1), the first comprehensive stochastic resonant NLSE model enabling the derivation of novel bright/dark/singular/Jacobi-elliptic soliton families and revealing noise-induced rogue waves and resonance-enhanced stability unobserved in prior deterministic or lower-order stochastic analyses.

While cubic and quintic nonlinearities are well-established in models of saturable media and multiphoton processes, the inclusion of septic (seventh-order) nonlinearity is critical for accurately describing systems exhibiting extreme nonlinear optical responses. Experimentally, septic effects become significant in: ultra-high intensity laser propagation in gases and plasmas, where higher-order Kerr terms are required to model ionization and harmonic generation beyond the perturbative regime, certain photorefractive crystals and colloidal suspensions, where saturation of the refractive index change follows a higher-order polynomial law, often measurable via z-scan techniques and dense Bose–Einstein condensates with strong beyond-mean-field corrections (e.g., Lee–Huang–Yang effects), where the expansion of the equation of state includes seventh-order density terms. Including the septic term in Eq. (1) thus allows the model to capture regimes where lower-order approximations break down, particularly in experiments involving high power densities or strongly interacting quantum fluids.

This paper proposes and analyzes a stochastic resonant nonlinear Schrödinger equation featuring cubic, quintic, and septic nonlocal nonlinearity Eq. (1). The model integrates chromatic dispersion, self-trapping dispersion (STD), intermodal dispersion (IMD), resonant nonlinearities, and multiplicative noise within the Itô framework. We utilize two complementary techniques to derive precise soliton solutions: Kudryashov’s algorithms [1,2] and the P^6 -model expansion approach [25–27]. These methods enable the derivation of new families of bright, dark, singular, Jacobi-elliptic, and periodic solitons.

Recent works have reported controlled shaping and deformation of bright, dark, chirped, W- and M-type solitons in nonlinear optical fibers through higher-order dispersion, birefringence, variable-coefficient effects, and nonlinear perturbations (see Refs. [42–48]). These studies

demonstrate that soliton characteristics can be significantly altered by parameter variations, external modulation, and structural changes in the governing equation. Motivated by these developments, our work considers a stochastic framework and examines how multiplicative perturbations influence soliton persistence, modulation behavior, and stability.

1.1. Main system

The dimensionless form of the stochastic resonant NLSE [1–9,15–22] is presented. It has a cubic-quintic-septic nonlocal law nonlinearity and both STD and IMD, as well as multiplicative noise in the itô sense.

$$i\Psi_t + a\Psi_{xx} + b\Psi_{xt} + [c_1|\Psi|^2 + c_2|\Psi|^4 + c_3|\Psi|^6 + c_4(|\Psi|^2)_{xx}] \Psi + \theta \left(\frac{|\Psi|_{xx}}{|\Psi|} \right) \Psi + \sigma (\Psi - ib\Psi_x) \frac{dW(t)}{dt} = i\alpha\Psi_x, \quad (1)$$

where the wave profile is represented by the complex-valued function $\Psi = \Psi(x, t)$, and the parameters $a, b, c_j, (j = 1, \dots, 4)$, γ, σ and α are real-valued constants with i^2 equal -1 . The first term of Eq. (1) is the linear temporal evolution, the chromatic dispersion (CD) and STD terms are symbolized by a and b , respectively. The parameters c_1, c_2 and c_3 supply the cubic-quintic-septic refractive index law, whereas c_4 provides the nonlocal law. After that, θ represents the coefficient of resonant nonlinearity, and α represents the coefficient of inter-modal dispersion (IMD). At last, white noise is $dW(t)/dt$, the standard Wiener approach is denoted by $W(t)$ and σ is the noise strength coefficient. The incorporation of the stochastic term $\sigma (\Psi - ib\Psi_x) \frac{dW(t)}{dt}$ in Eq. (1) is intended to formulate a stochastic differential equation applicable across various disciplines, including physics, engineering, biology, and chemistry, which accounts for temporal noise or fluctuations. The non-local nonlinearity term $c_4(|\Psi|^2)_{xx} \Psi$ arises from a convolution model $n_{nl} = \int R(x - x') |\Psi(x')|^2 dx'$, where $R(x)$ is a symmetric response kernel (e.g., Gaussian or exponential). Expanding n_{nl} to the second order yields the differential approximation used in Eq. (1), with c_4 proportional to the second moment of $R(x)$. The spatial width σ_R of the kernel determines the degree of nonlocality:

For σ_R much larger than the soliton width, nonlinear interactions are strongly smoothed, suppressing beam collapse and stabilizing solitons against small-scale perturbations.

As $\sigma_R \rightarrow 0$, the model reduces to a local cubic-quintic-septic system, where collapse instabilities can dominate. Thus, the sign and magnitude of c_4 effectively control the stabilizing influence of nonlocality in our solutions. This mechanism is especially relevant in nematic liquid crystals, thermal optical media, and dipolar Bose–Einstein condensates, where nonlocal responses are experimentally tunable.

This article consists of the following: Section 2 delineates the first procedures. In this third section, we will resolve Eq. (1) utilizing Kudryashov's algorithm and the P^6 -model expansion method. Section four will show numerical simulations. Physical interpretations are presented in Section 5. Section 6 contains the Discussion and Conclusions.

2. Preliminary steps

The objective is to uncover soliton solutions to Eq. (1). For this objective, we outline the transformation below:

$$\Psi(x, t) = F(\zeta) \exp[i(-\kappa x + \omega t + \sigma W(t) - \sigma^2 t)], \quad \zeta = \mu x - \beta t. \quad (2)$$

In this context, κ, ω, μ and β represent non-zero constants. In this context, ω represents the wave number, μ signifies the spatial variable, β denotes the soliton's velocity, and κ indicates the soliton's frequency. The function $F(\zeta)$ constrains the amplitude component. Substituting Eq. (2) into Eq. (1) and separating the real and imaginary components results in

$$\Re : L_1 F''(\zeta) - L_2 F(\zeta) + c_1 F^3(\zeta) + c_2 F^5(\zeta) + c_3 F^7(\zeta) + 2\mu^2 c_4 [F(\zeta) F'^2(\zeta) + F^2(\zeta) F''(\zeta)] = 0, \quad (3)$$

as well

$$\Im : -[\beta(1 - b\kappa) + \mu(2a\kappa - b(\omega - \sigma^2) + \alpha)] F'(\zeta) = 0. \quad (4)$$

From Eq. (4), we get the soliton's velocity

$$\beta = -\frac{\mu[\alpha + 2a\kappa - b(\omega - \sigma^2)]}{(1 - b\kappa)}, \quad (5)$$

we balance $F^2(\zeta) F''(\zeta)$ with $F^7(\zeta)$ in Eq. (3), we get:

$$2M + M + 2 = 7M \rightarrow M = \frac{1}{2}. \quad (6)$$

Here is the transformation that we employ:

$$F(\zeta) = Z^{\frac{1}{2}}(\zeta). \quad (7)$$

Rewrite Eq. (3) as

$$L_1(2Z(\zeta) Z''(\zeta) - Z'^2(\zeta)) - 4L_2 Z^2(\zeta) + 4c_1 Z^3(\zeta) + 4c_2 Z^4(\zeta) + 4c_3 Z^5(\zeta) + 4\mu^2 c_4 Z^2(\zeta) Z''(\zeta) = 0, \quad (8)$$

where

$$L_1 = \frac{(a + \theta)(1 - b\kappa)\mu^2 + b\mu^2[\alpha + 2a\kappa - b(\omega - \sigma^2)]}{(1 - b\kappa)}, \quad (9)$$

$$L_2 = \alpha\kappa + a\kappa^2 + (1 - b\kappa)(\omega - \sigma^2).$$

The subsequent section will elaborate on the techniques used to address Eq. (8).

3. Novel soliton solutions

In this section, Eq. (8) is analyzed using the subsequent techniques in the following subsections:

3.1. Addendum kudryashov's algorithm

Applying the preceding technique [1,2], assume Eq. (8) has a meaningful solution:

$$Z(\zeta) = \sum_{s=0}^M \sigma_s R^s(\zeta), \quad \theta_M \neq 0. \quad (10)$$

In addition, the $R(\zeta)$ function fits the ODE:

$$R'^2(\zeta) = R^2(\zeta) [1 - \delta R^{2g}(\zeta)] \ln^2(A), \quad 0 < a \neq 1. \quad (11)$$

In this setting, σ_s ($s = 0, \dots, M$) and δ are variables, while g represents a positive integer. When we balance $Z^2(\zeta) Z''(\zeta)$ with $Z^5(\zeta)$ in Eq. (8), we arrive at:

$$Z^2(\zeta) \rightarrow 2M, \quad Z''(\zeta) = M + 2g \& Z^5(\zeta) \rightarrow 5M \rightarrow 2M + M + 2g = 5M \Rightarrow M = g. \quad (12)$$

Currently let's address each of these forms:

Form.I. Given $g = 1, M = 1$. In place is the systematic solution:

$$Z(\zeta) = \sigma_1 R(\zeta) + \sigma_0, \quad \sigma_1 \neq 0, \quad (13)$$

alongside

$$R'^2(\zeta) = R^2(\zeta) [1 - \delta R^2(\zeta)] \ln^2(A), \quad 0 < a \neq 1. \quad (14)$$

Generally, Eq. (14) has a bright-singular soliton:

$$R(\zeta) = \left[\frac{4K}{(4K^2 + \delta) \cosh[(g\zeta) \ln A] + (4K^2 - \delta) \sinh[(g\zeta) \ln A]} \right]^{\frac{1}{g}}, K \neq 0. \quad (15)$$

Changing (13), (14) in (8) yields the following algebraic equations

$$\left. \begin{aligned} R^5(\zeta) : -4\sigma_1^3 (2\delta\mu^2 c_4 \ln^2(A) - c_3\sigma_1^2) &= 0, \\ R^4(\zeta) : -16\ln^2(A) \delta\mu^2 c_4 \sigma_0 \sigma_1^2 - 3\ln^2(A) \delta L_1 \sigma_1^2 + 20c_3 \sigma_0 \sigma_1^4 + 4c_2 \sigma_1^4 &= 0, \\ R^3(\zeta) : -8\ln^2(A) \delta\mu^2 c_4 \sigma_0^2 \sigma_1 + 4\ln^2(A) \mu^2 c_4 \sigma_1^3 - 4\ln^2(A) \delta L_1 \sigma_0 \sigma_1 \\ &+ 40c_3 \sigma_0^2 \sigma_1^3 + 16c_2 \sigma_0 \sigma_1^3 + 4c_1 \sigma_1^3 = 0, \\ R^2(\zeta) : 8\ln^2(A) \mu^2 c_4 \sigma_0 \sigma_1^2 + 40c_3 \sigma_0^3 \sigma_1^2 + \ln^2(A) L_1 \sigma_1^2 + 24c_2 \sigma_0^2 \sigma_1^2 \\ &+ 12c_1 \sigma_0 \sigma_1^2 - 4L_2 \sigma_1^2 = 0, \\ R(\zeta) : 4\ln^2(A) \mu^2 c_4 \sigma_0^2 \sigma_1 + 20c_3 \sigma_0^4 \sigma_1 + 2\ln^2(A) L_1 \sigma_0 \sigma_1 + 16c_2 \sigma_0^3 \sigma_1 \\ &+ 12c_1 \sigma_0^2 \sigma_1 - 8L_2 \sigma_0 \sigma_1 = 0, \\ R^0(\zeta) : 4c_3 \sigma_0^5 + 4c_2 \sigma_0^4 + 4c_1 \sigma_0^3 - 4L_2 \sigma_0^2 &= 0. \end{aligned} \right\} \quad (16)$$

Thus, Eq. (16) hold the results:

$$\begin{aligned} c_1 &= \frac{(17L_1 \ln^2(A) + 20L_2) \mu^2 c_4 \ln^2(A)}{(5L_1 \ln^2(A) + 4L_2)}, \\ c_2 &= -\frac{12(9L_1 \ln^2(A) + 8L_2) \mu^4 c_4^2 \ln^4(A)}{(5L_1 \ln^2(A) + 4L_2)^2}, \\ c_3 &= \frac{32\mu^6 c_4^3 \ln^6(A)}{(5L_1 \ln^2(A) + 4L_2)^2}, \sigma_0 = \frac{(5L_1 \ln^2(A) + 4L_2)}{4\mu^2 c_4 \ln^2(A)}, \\ \sigma_1 &= \frac{\sqrt{\delta}(5L_1 \ln^2(A) + 4L_2)}{4\mu^2 c_4 \ln^2(A)}. \end{aligned} \quad (17)$$

Given $\delta > 0$. Inputting (17) and (15) into (13) completes the combo bright-singular soliton:

$$\Psi(x, t) = \left\{ \frac{(5L_1 \ln^2(A) + 4L_2)}{4\mu^2 c_4 \ln^2(A)} \times \left[1 + \frac{4\sqrt{\delta}K}{(4K^2 + \delta) \cosh(\zeta \ln A) + (4K^2 - \delta) \sinh(\zeta \ln A)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}. \quad (18)$$

The bright soliton originates at $\delta = 4K^2$.

$$\Psi(x, t) = \left\{ \frac{(5L_1 \ln^2(A) + 4L_2)}{4\mu^2 c_4 \ln^2(A)} [1 + \operatorname{sech}(\zeta \ln A)] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}. \quad (19)$$

Form.II. Select $g = 2$ initially, followed by $M = 2$. Below is what we received:

$$Z(\zeta) = \sigma_2 R^2(\zeta) + \sigma_1 R(\zeta) + \sigma_0, \quad \sigma_2 \neq 0, \quad (20)$$

as well as

$$R'^2(\zeta) = R^2(\zeta) [1 - \delta R^4(\zeta)] \ln^2(A), \quad 0 < a \neq 1. \quad (21)$$

By inserting (20, 21) in (8), algebraic equations result as follows:

$$\left. \begin{aligned} R^{10}(\zeta) : -32\ln^2(A) \delta\mu^2 c_4 \sigma_2^3 + 4c_3 \sigma_2^5 &= 0, \\ R^9(\zeta) : -76\ln^2(A) \delta\mu^2 c_4 \sigma_1 \sigma_2^2 + 20c_3 \sigma_1 \sigma_2^4 &= 0, \\ R^8(\zeta) : -64\ln^2(A) \delta\mu^2 c_4 \sigma_0 \sigma_2^2 - 56\ln^2(A) \delta\mu^2 c_4 \sigma_1^2 \sigma_2 \\ &- 12\ln^2(A) \delta L_1 \sigma_2^2 + 20c_3 \sigma_0 \sigma_2^4 + 40c_3 \sigma_1^2 \sigma_2^3 + 4c_2 \sigma_2^4 = 0, \\ R^7(\zeta) : -88\ln^2(A) \delta\mu^2 c_4 \sigma_0 \sigma_1 \sigma_2 - 12\ln^2(A) \delta\mu^2 c_4 \sigma_1^3 \\ &- 18\ln^2(A) \delta L_1 \sigma_1 \sigma_2 + 80c_3 \sigma_0 \sigma_1 \sigma_2^2 + 40c_3 \sigma_1^3 \sigma_2^2 + 16c_2 \sigma_1 \sigma_2^3 = 0, \\ R^6(\zeta) : -32\ln^2(A) \delta\mu^2 c_4 \sigma_0^2 \sigma_2 - 24\ln^2(A) \delta\mu^2 c_4 \sigma_0 \sigma_1^2 \\ &+ 16\ln^2(A) \mu^2 c_4 \sigma_2^3 - 16\ln^2(A) \delta L_1 \sigma_0 \sigma_2 \\ &- 5\ln^2(A) \delta L_1 \sigma_1^2 + 40c_3 \sigma_0^2 \sigma_2^3 + 120c_3 \sigma_0 \sigma_1^2 \sigma_2^2 + 20c_3 \sigma_1^4 \sigma_2 \\ &+ 16c_2 \sigma_0 \sigma_2^3 + 24c_2 \sigma_1^2 \sigma_2^2 + 4c_1 \sigma_2^3 = 0, \\ R^5(\zeta) : -12\ln^2(A) \delta\mu^2 c_4 \sigma_0^2 \sigma_1 + 36\ln^2(A) \mu^2 c_4 \sigma_1 \sigma_2^2 \\ &- 6\ln^2(A) \delta L_1 \sigma_0 \sigma_1 + 120c_3 \sigma_0^2 \sigma_1 \sigma_2^2 \\ &+ 80c_3 \sigma_0 \sigma_1^3 \sigma_2 + 4c_3 \sigma_1^5 + 48c_2 \sigma_0 \sigma_1 \sigma_2^2 + 16c_2 \sigma_1^3 \sigma_2 + 12c_1 \sigma_1 \sigma_2^2 = 0, \\ R^4(\zeta) : 32\ln^2(A) \mu^2 c_4 \sigma_0 \sigma_2^2 + 24\ln^2(A) \mu^2 c_4 \sigma_1^2 \sigma_2 \\ &+ 40c_3 \sigma_0^2 \sigma_2^2 + 120c_3 \sigma_0^2 \sigma_1^2 \sigma_2 + 20c_3 \sigma_0^4 \sigma_2 \\ &+ 4\ln^2(A) L_1 \sigma_2^2 + 24c_2 \sigma_0^2 \sigma_2^2 + 48c_2 \sigma_0 \sigma_1^2 \sigma_2 + 4c_2 \sigma_1^4 + 12c_1 \sigma_0 \sigma_2^2 \\ &+ 12c_1 \sigma_1^2 \sigma_2 - 4L_2 \sigma_2^2 = 0, \\ R^3(\zeta) : 40\ln^2(A) \mu^2 c_4 \sigma_0 \sigma_1 \sigma_2 + 4\ln^2(A) \mu^2 c_4 \sigma_1^3 + 80c_3 \sigma_0^3 \sigma_1 \sigma_2 \\ &+ 40c_3 \sigma_0^2 \sigma_1^3 + 6\ln^2(A) L_1 \sigma_1 \sigma_2 \\ &+ 48c_2 \sigma_0^2 \sigma_1 \sigma_2 + 16c_2 \sigma_0 \sigma_1^3 + 24c_1 \sigma_0 \sigma_1 \sigma_2 + 4c_1 \sigma_1^3 - 8L_2 \sigma_1 \sigma_2 = 0, \\ R^2(\zeta) : 16\ln^2(A) \mu^2 c_4 \sigma_0^2 \sigma_2 + 8\ln^2(A) \mu^2 c_4 \sigma_0 \sigma_1^2 + 20c_3 \sigma_0^4 \sigma_2 \\ &+ 40c_3 \sigma_0^3 \sigma_1^2 + 8\ln^2(A) L_1 \sigma_0 \sigma_2 \\ &+ \ln^2(A) L_1 \sigma_1^2 + 16c_2 \sigma_0^3 \sigma_2 + 24c_2 \sigma_0^2 \sigma_1^2 + 12c_1 \sigma_0^2 \sigma_2 + 12c_1 \sigma_0 \sigma_1^2 \\ &- 8L_2 \sigma_0 \sigma_2 - 4L_2 \sigma_1^2 = 0, \\ R(\zeta) : 4\ln^2(A) \mu^2 c_4 \sigma_0^2 \sigma_1 + 20c_3 \sigma_0^4 \sigma_1 + 2\ln^2(A) L_1 \sigma_0 \sigma_1 + 16c_2 \sigma_0^3 \sigma_1 \\ &+ 12c_1 \sigma_0^2 \sigma_1 - 8L_2 \sigma_0 \sigma_1 = 0, \\ R^0(\zeta) : 4c_3 \sigma_0^5 + 4c_2 \sigma_0^4 + 4c_1 \sigma_0^3 - 4L_2 \sigma_0^2 &= 0. \end{aligned} \right\} \quad (22)$$

Thus, Eq. (22) hold the results:

$$\begin{aligned} c_1 &= \frac{4(17L_1 \ln^2(A) + 5L_2) \mu^2 c_4 \ln^2(A)}{(5L_1 \ln^2(A) + L_2)}, \\ c_2 &= -\frac{48(9L_1 \ln^2(A) + 2L_2) \mu^4 c_4^2 \ln^4(A)}{(5L_1 \ln^2(A) + L_2)^2}, \\ c_3 &= \frac{128\mu^6 c_4^3 \ln^6(A)}{(5L_1 \ln^2(A) + L_2)^2}, \sigma_0 = \frac{(5L_1 \ln^2(A) + L_2)}{4\mu^2 c_4 \ln^2(A)}, \\ \sigma_1 &= 0, \sigma_2 = \frac{\sqrt{\delta}(5L_1 \ln^2(A) + L_2)}{4\mu^2 c_4 \ln^2(A)}. \end{aligned} \quad (23)$$

Inputting (15) and (23) into (21) completes the combo bright-singular soliton:

$$\Psi(x, t) = \left\{ \frac{(5L_1 \ln^2(A) + L_2)}{4\mu^2 c_4 \ln^2(A)} \times \left[1 + \frac{4\sqrt{\delta}K}{(4K^2 + \delta) \cosh(2\zeta \ln A) + (4K^2 - \delta) \sinh(2\zeta \ln A)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]} \quad (24)$$

The bright soliton originates at $\delta = 4K^2$

$$\Psi(x, t) = \left\{ \frac{(5L_1 \ln^2(A) + L_2)}{4\mu^2 c_4 \ln^2(A)} [1 + \operatorname{sech}(2\zeta \ln A)] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]} \quad (25)$$

By varying g and M , Eq. (12) can yield numerous soliton solutions.

3.2. P^6 -model expansion approach

In Eq. (8), balancing $Z^2(\zeta)$ $Z''(\zeta)$ with $Z^5(\zeta)$ yields the equilibrium number $M = 1$. Eq. (8) has a formalized solution [25–27].

$$Z(\zeta) = K_2 P^2(\zeta) + K_1 P(\zeta) + K_0, \quad K_2 \neq 0, \quad (26)$$

and $P(\zeta)$ satisfies:

$$P'^2(\zeta) = \Pi_6 P^6(\zeta) + \Pi_4 P^4(\zeta) + \Pi_2 P^2(\zeta) + \Pi_0, \quad (27)$$

here K_0, K_1, K_2 and Π_l ($l = 0, 2, 4$ & 6) are the parameters. Use the solution as a guide.

$$P(\zeta) = \frac{\eta(\zeta)}{\sqrt{M_1 \eta^2(\zeta) + M_2}}. \quad (28)$$

The solution to the Jacobi elliptic equation is $\eta(\zeta)$:

$$\eta^2(\zeta) = \chi_0 + \chi_2 \eta^2(\zeta) + \chi_4 \eta^4(\zeta), \quad (29)$$

χ_r (where $r = 0, 2$ and 4) are parameters, and M_1 and M_2 are values given by

$$M_1 = \frac{\Pi_4 (\chi_2 - \Pi_2)}{(\chi_2 - \Pi_2)^2 - 2\chi_2 (\chi_2 - \Pi_2) + 3\chi_0 \chi_4}, \quad (30)$$

$$M_2 = \frac{3\chi_0 \Pi_4}{(\chi_2 - \Pi_2)^2 - 2\chi_2 (\chi_2 - \Pi_2) + 3\chi_0 \chi_4},$$

within the confines of

$$\Pi_4^2 (\chi_2 - \Pi_2) [9\chi_4 \chi_0 - (2\chi_2 + \Pi_2) (\chi_2 - \Pi_2)] + 3\Pi_6 [3\chi_0 \chi_4 - (\chi_2 - \Pi_2^2)]^2 = 0, \quad (31)$$

$$\chi_2 \neq \Pi_2.$$

Changing (26), (27) in (8) yields the following algebraic equations

$$\left. \begin{aligned} P^{10}(\zeta) : 32c_4\mu^2 K_2^3 \Pi_6 + 4K_2^5 c_3 &= 0, \\ P^9(\zeta) : 76\mu^2 c_4 K_1 K_2^2 \Pi_6 + 20K_1 K_2^4 c_3 &= 0, \\ P^8(\zeta) : 4c_2 K_2^4 + 4c_3 (K_0 K_2^4 + 4K_1^2 K_2^3 + 2K_2^3 (2K_0 K_2 + 3K_1^2)) \\ &+ 32\mu^2 c_4 (2K_0 K_2 + K_1^2) K_2 \Pi_6 \\ &+ 12L_1 K_2^2 \Pi_6 + 24\mu^2 c_4 K_1^2 K_2 \Pi_6 + 24\mu^2 c_4 K_2^3 \Pi_4 = 0, \\ P^7(\zeta) : 12\mu^2 c_4 (2K_0 K_2 + K_1^2) K_1 \Pi_6 + 4c_3 (4K_0 K_1 K_2^3 \\ &+ 2K_1 K_2^2 (2K_0 K_2 + 3K_1^2) + 4K_1 K_2^2 (3K_0 K_2 + K_1^2) \\ &+ 16c_2 K_1 K_2^3 + 18L_1 K_1 K_2 \Pi_6 + 64\mu^2 c_4 K_0 K_1 K_2 \Pi_6 \\ &+ 56\mu^2 c_4 K_1 K_2^2 \Pi_4 = 0, \\ P^6(\zeta) : 32\mu^2 K_0^2 K_2 \Pi_6 c_4 + 24\mu^2 K_0 K_1^2 \Pi_6 c_4 + 48\mu^2 K_0 K_2^2 \Pi_4 c_4 \\ &+ 40\mu^2 K_1^2 K_2 \Pi_4 c_4 + 16\mu^2 K_2^3 \Pi_2 c_4 \\ &+ 40K_0^2 K_2^3 c_3 + 120K_0 K_1^2 K_2^2 c_3 + 20K_1^4 K_2 c_3 \\ &+ 16K_0 K_2^3 c_2 + 24K_1^2 K_2^2 c_2 + 16K_0 K_2 L_1 \Pi_6 \\ &+ 5K_1^2 L_1 \Pi_6 + 4K_2^3 c_1 + 8K_2^2 L_1 \Pi_4 = 0, \\ P^5(\zeta) : 2K_1 (6\mu^2 K_0^2 \Pi_6 c_4 + 32\mu^2 K_0 K_2 \Pi_4 c_4 + 4\mu^2 K_1^2 \Pi_4 c_4 \\ &+ 18\mu^2 K_2^2 \Pi_2 c_4 + 60K_0^2 K_2^2 c_3 + 2K_1^4 c_3) \\ &+ 2K_1 (24K_0 K_2^2 c_2 + 8K_1^2 K_2 c_2 + 6K_2^2 c_1 + 3(K_0 \Pi_6 + 2K_2 \Pi_4) L_1 \\ &+ 40K_0 K_1^2 K_2 c_3) = 0, \\ P^4(\zeta) : 24\mu^2 K_0^2 K_2 \Pi_4 c_4 + 16\mu^2 K_0 K_1^2 \Pi_4 c_4 + 32\mu^2 K_0 K_2^2 \Pi_2 c_4 \\ &+ 24\mu^2 K_1^2 K_2 \Pi_2 c_4 + 8\mu^2 K_2^3 \Pi_0 c_4 \\ &+ 120K_0^2 K_1^2 K_2 c_3 + 20K_0 K_1^4 c_3 + 24K_0^2 K_2^2 c_2 + 48K_0 K_1^2 K_2 c_2 \\ &+ 4K_1^4 c_2 + 12K_0 K_2^2 c_1 + 40K_0^3 K_2^2 c_3 \\ &+ 12K_1^2 K_2 c_1 + (3K_1^2 \Pi_4 + 4K_2^2 \Pi_2 + 12K_0 K_2 \Pi_4) L_1 - 4K_2^2 L_2 = 0, \\ P^3(\zeta) : 2K_1 (4\mu^2 K_0^2 \Pi_4 c_4 + 20\mu^2 K_0 K_2 \Pi_2 c_4 + 2\mu^2 K_1^2 \Pi_2 c_4 \\ &+ 8\mu^2 K_2^2 \Pi_0 c_4 + 40K_0^3 K_2 c_3 + 24K_0^2 K_2 c_2) \\ &+ 2K_1 (8K_0 K_1^2 c_2 + 12K_0 K_2 c_1 \\ &+ 20K_0^2 K_1^2 c_3 - 4K_2 L_2) + 2K_1 [(2K_0 + 3K_2 \Pi_2) \\ &+ L_1 \Pi_4 + 2K_1^2 c_1] = 0, \\ P^2(\zeta) : 16\mu^2 K_0^2 K_2 \Pi_2 c_4 + 8\mu^2 K_0 K_1^2 \Pi_2 c_4 + 16\mu^2 K_0 K_2^2 \Pi_0 c_4 \\ &+ 8\mu^2 K_1^2 K_2 \Pi_0 c_4 + 20K_0^4 K_2 c_3 \\ &+ 40K_0^3 K_1^2 c_3 + 16K_0^3 K_2 c_2 + 24K_0^2 K_1^2 c_2 \\ &+ 12K_0^2 K_2 c_1 + 12K_0 K_1^2 c_1 + 8K_0 K_2 L_1 \Pi_2 \\ &+ K_1^2 L_1 \Pi_2 - 4(2K_0 K_2 + K_1^2) L_2 = 0, \\ P(\zeta) : 2K_0 K_1 (2\mu^2 K_0 \Pi_2 c_4 + L_1 \Pi_2 - 4L_2) \\ &+ 4K_0 K_1 (4\mu^2 K_2 \Pi_0 c_4 + 5K_0^3 c_3 + 4K_0^2 c_2 + 3K_0 c_1) = 0, \\ P^0(\zeta) : L_1 (4K_0 K_2 \Pi_0 - K_1^2 \Pi_0) - 4K_0^2 L_2 + 4K_0^3 c_1 + 4K_0^4 c_2 + 4K_0^5 c_3 \\ &+ 8\mu^2 K_0^2 K_2 \Pi_0 c_4 = 0. \end{aligned} \right\} \quad (32)$$

Thus, Eqs. (32) hold the results:

$$K_0 = 0, K_1 = 0, K_2 = \frac{(L_2 - L_1 \Pi_2)}{2\mu^2 \Pi_0 c_4}, \Pi_0 = \Pi_0, \Pi_2 = \Pi_2,$$

$$\Pi_4 = -\frac{(8\mu^2 c_2 c_4 - 3L_1 c_3) (L_2 - L_1 \Pi_2)}{96\mu^6 c_4^3 \Pi_0}, \Pi_6 = -\frac{c_3 (L_2 - L_1 \Pi_2)^2}{32\mu^6 c_4^3 \Pi_0^2},$$

$$c_1 = -\frac{96\mu^6\Pi_2c_4^3 - 8\mu^2L_1c_2c_4 + 3L_1^2c_3}{24\mu^4c_4^2}. \quad (33)$$

Combining (33), (26), and (28) yields the following JEF solutions:

$$F(\zeta) = \left\{ \frac{(L_2 - L_1\Pi_2)}{2\mu^2\Pi_0c_4} \left[\frac{\eta^2(\zeta)}{M_1\eta^2(\zeta) + M_2} \right] \right\}^{\frac{1}{2}}. \quad (34)$$

We will announce the updated preliminary families. **Family-I.** When $\eta(\zeta) = \text{sn}(\zeta, m)$ or $\text{cd}(\zeta, m)$, and $0 < m < 1$, $\chi_0 = 1$, $\chi_2 = -(1 + m^2)$, $\chi_4 = m^2$. Right now, we show:

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{sn}^2(\zeta, m)}{(1 + m^2 + \Pi_2)\text{sn}^2(\zeta, m) - 3} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (35)$$

or

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{cd}^2(\zeta, m)}{(1 + m^2 + \Pi_2)\text{cd}^2(\zeta, m) - 3} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (36)$$

within the bounds of this restriction

$$\Pi_4^2 (1 + m^2 + \Pi_2) [9m^2 - (2 + 2m^2 - \Pi_2) (1 + m^2 + \Pi_2)] - 3\Pi_6 [3m^2 + (1 + m^2 + \Pi_2)]^2 = 0, \quad \chi_2 \neq \Pi_2, \quad (37)$$

whereas Π_6 & Π_4 offered by (33). In addition to $m \rightarrow 1^-$, a dark soliton showed up:

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(\Pi_2^2 - 1)\tanh^2(\zeta)}{(2 + \Pi_2)\tanh^2(\zeta) - 3} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (38)$$

under the constraint condition

$$\Pi_4^2 (\Pi_2 + 2) - 3\Pi_6(\Pi_2 + 1)^2 = 0. \quad (39)$$

When m approaches zero, the periodic solutions become visible.

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{\Pi_2^2 - 1}{(1 + \Pi_2) - 3\csc^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (40)$$

as well as

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{\Pi_2^2 - 1}{(1 + \Pi_2) - 3\sec^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (41)$$

within constraints

$$\Pi_4^2 (\Pi_2 - 2) - 3\Pi_6(\Pi_2 - 1)^2 = 0, \quad \Pi_2 \neq \pm 1. \quad (42)$$

Family-II. In the event that $\chi_0 = m^2$, $\chi_4 = 1$, $\chi_2 = -(1 + m^2)$, and $\eta(\zeta) = \text{dc}(\zeta, m)$ or $\text{ns}(\zeta, m)$, then:

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{dc}^2(\zeta, m)}{(1 + m^2 + \Pi_2)\text{dc}^2(\zeta, m) - 3m^2} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (43)$$

as well as

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{ns}^2(\zeta, m)}{(1 + m^2 + \Pi_2)\text{ns}^2(\zeta, m) - 3m^2} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (44)$$

keeping this restriction (37) in mind. To obtain the singular solitons, set $m \rightarrow 1^-$.

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(\Pi_2^2 - 1)\coth^2(\zeta)}{(2 + \Pi_2)\coth^2(\zeta) - 3} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (45)$$

with the identical restriction (39) and $\Pi_2 \neq \pm 1$.

Family-III. When $\chi_0 = -m^2$, $\chi_2 = 2m^2 - 1$, and $\chi_4 = 1 - m^2$, the JEF solutions are satisfied by $\eta(\zeta) = \text{nc}(\zeta, m)$ and Eq. (1).

$$\Psi(x, t) = \left\{ -\frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{nc}^2(\zeta, m)}{(2m^2 - 1 - \Pi_2)\text{nc}^2(\zeta, m) - 3m^2} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (46)$$

within the condition of constraint

$$\Pi_4^2 (2m^2 - 1 - \Pi_2) [9m^2(1 - m^2) + (2m^2 - 1 - \Pi_2) (4m^2 - 2 + \Pi_2)] + 3\Pi_6 [3m^2(1 - m^2) + (2m^2 - 1)^2 - \Pi_2^2] = 0. \quad (47)$$

When $m \rightarrow 1^-$, bright solitons are maintained.

$$\Psi(x, t) = \left\{ \frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{\Pi_2^2 - 1}{3\text{sech}^2(\zeta) - (1 - \Pi_2)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (48)$$

under the constraint condition

$$\Pi_4^2 (\Pi_2 + 2) + 3\Pi_6(\Pi_2 + 1)^2 = 0, \quad \Pi_2 \neq \pm 1. \quad (49)$$

Family-IV. With $\chi_0 = 1$, $\chi_2 = 2 - m^2$, $\chi_4 = 1 - m^2$ and $\eta(\zeta) = \text{sc}(\zeta, m)$ and we achieve

$$\Psi(x, t) = \left\{ -\frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{sc}^2(\zeta, m)}{(2 - m^2 - \Pi_2)\text{sc}^2(\zeta, m) + 3} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (50)$$

under the same constraint condition

$$\Pi_4^2 (2 - m^2 - \Pi_2) [9(m^2 - 1) + (2 - m^2 - \Pi_2) (4 - 2m^2 + \Pi_2)] + 3\Pi_6 [3(m^2 - 1) + (2 - m^2)^2 - \Pi_2^2] = 0. \quad (51)$$

For $m \rightarrow 1^-$, holding the singular soliton provides:

$$\Psi(x, t) = \left\{ -\frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{\Pi_2^2 - 1}{(1 - \Pi_2) + 3\text{csch}^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (52)$$

provided the same condition (49). Putting m close to zero will yield the periodic solution.

$$\Psi(x, t) = \left\{ -\frac{48\mu^4c_4^2}{(8\mu^2c_2c_4 - 3L_1c_3)} \left[\frac{(\Pi_2^2 - 1)\tan^2(\zeta)}{3 + (2 - \Pi_2)\tan^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (53)$$

under the constraint condition

$$-\Pi_4^2 (\Pi_2 - 2) + 3\Pi_6(\Pi_2 - 1)^2 = 0, \Pi_2 \neq \pm 1. \quad (54)$$

Family-V. We benefit from $\eta(\zeta) = \text{cs}(\zeta, m)$ if and only if $\chi_4 = 1, \chi_2 = 2 - m^2$ and $\chi_0 = 1 - m^2$, then, we gain

$$\Psi(x, t) = \left\{ -\frac{48\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{cs}^2(\zeta, m)}{(2 - m^2 - \Pi_2)\text{cs}^2(\zeta, m) + 3(1 - m^2)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (55)$$

in the situation of constraint

$$\begin{aligned} & \Pi_4^2 (2 - m^2 - \Pi_2) [9(m^2 - 1) + (2 - m^2 - \Pi_2)(4 - 2m^2 + \Pi_2)] \\ & + 3\Pi_6 [3(m^2 - 1) + (2 - m^2)^2 - \Pi_2^2]^2 = 0. \end{aligned} \quad (56)$$

When $m \rightarrow 0^+$, the periodic solution appears as:

$$\Psi(x, t) = \left\{ -\frac{48\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(\Pi_2^2 - 1)\cot^2(\zeta)}{3 + (2 - \Pi_2)\cot^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (57)$$

With the constraint condition (54) and $\Pi_2 \neq \pm 1$.

Family-VI. If $\chi_0 = \frac{1}{4}, \chi_2 = \frac{1 - m^2}{2}, \chi_4 = \frac{1}{4}$, then $\eta(\zeta) = \frac{\text{sn}(\zeta, m)}{1 \pm \text{cn}(\zeta, m)}$, we also keep up with the JEF solutions.

$$\Psi(x, t) = \left\{ \frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(16m^4 - 16m^2 - 16\Pi_2^2 + 1)\text{sn}^2(\zeta, m)}{3[1 \pm \text{cn}(\zeta, m)]^2 + 2(1 - 2m^2 - 2\Pi_2)\text{sn}^2(\zeta, m)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (58)$$

under the constraint condition

$$\begin{aligned} & 8\Pi_4^2 (1 - 2m^2 - 2\Pi_2) [9 - 8(1 - 2m^2 - 2\Pi_2)(1 - 2m^2 + \Pi_2)] \\ & + 3\Pi_6 [3 - 4(1 - 2m^2)^2 + 16\Pi_2^2]^2 = 0. \end{aligned} \quad (59)$$

When m approaches 1^- , maintain combination solitons.

$$\Psi(x, t) = \left\{ \frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(1 - 16\Pi_2^2)\tanh^2(\zeta)}{3[1 \pm \text{sech}(\zeta)]^2 - 2(1 + 2\Pi_2)\tanh^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (60)$$

under the constraint condition

$$-8\Pi_4^2 (1 + 2\Pi_2) + 3\Pi_6 (4\Pi_2 + 1)^2 = 0, \Pi_2 \neq \pm \frac{1}{4}. \quad (61)$$

For obtaining periodic solutions, set m to zero:

$$\Psi(x, t) = \left\{ \frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(1 - 16\Pi_2^2)\tan^2(\zeta)}{3[\text{sech}(\zeta) \pm 1]^2 + 2(1 - 2\Pi_2)\tan^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (62)$$

under the constraint condition

$$-8\Pi_4^2 (1 - 2\Pi_2) + 3\Pi_6 (4\Pi_2 - 1)^2 = 0, \Pi_2 \neq \pm \frac{1}{4}. \quad (63)$$

Family-VII. If $\chi_0 = \frac{1}{4}, \chi_2 = \frac{1 + m^2}{2}, \chi_4 = \frac{(1 - m^2)^2}{4}$, then $\eta(\zeta) = \frac{\text{sn}(\zeta, m)}{\text{cn}(\zeta, m) \pm \text{dn}(\zeta, m)}$ and we own the JEF solutions

$$\Psi(x, t) = \left\{ -\frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(m^4 + 14m^2 - 16\Pi_2^2 + 1)\text{sn}^2(\zeta, m)}{3[\text{cn}(\zeta, m) \pm \text{dn}(\zeta, m)]^2 + 2(1 + m^2 - 2\Pi_2)\text{sn}^2(\zeta, m)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (64)$$

within a condition of constraint

$$\begin{aligned} & 8\Pi_4^2 (1 + m^2 - 2\Pi_2) [9(1 - m^2)^2 - 8(1 + m^2 - 2\Pi_2)(1 + m^2 + \Pi_2)] \\ & + 3\Pi_6 [3(1 - m^2)^2 - 4(1 + m^2)^2 + 16\Pi_2^2]^2 = 0. \end{aligned} \quad (65)$$

Using $m \rightarrow 1^-$, yields the following singular solitons:

$$\Psi(x, t) = \left\{ -\frac{48\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(1 - \Pi_2^2)\tanh^2(\zeta)}{3\text{sech}^2(\zeta) + (1 - \Pi_2)\tanh^2(\zeta)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (66)$$

under the same constraint condition (39) & $\Pi_2 \neq \pm 1$. To maintain the same periodic solutions (62) with m near 0^+ ,

Family-VIII. If $\chi_0 = 1 - m^2, \chi_2 = 2m^2 - 1, \eta(\zeta) = \text{cn}(\zeta, m)$ & $\chi_4 = -m^2$, we get

$$\Psi(x, t) = \left\{ -\frac{48\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{cn}^2(\zeta, m)}{(2m^2 - 1 - \Pi_2)\text{cn}^2(\zeta, m) + 3(1 - m^2)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (67)$$

under the constraint condition

$$\begin{aligned} & -\Pi_4^2 (2m^2 - 1 - \Pi_2) [9m^2(1 - m^2) + (2m^2 - 1 - \Pi_2)(4m^2 - 2 + \Pi_2)] \\ & + 3\Pi_6 [-3m^2(1 - m^2) - (2m^2 - 1)^2 + \Pi_2^2]^2 = 0. \end{aligned} \quad (68)$$

After setting $m \rightarrow 0^+$, (1) maintains the same periodic solution (42).

Family-IX. If $\chi_0 = -m^2(1 - m^2), \eta(\zeta) = \text{ds}(\zeta, m), \chi_2 = 2m^2 - 1$ and χ_4 equals unity, then

$$\Psi(x, t) = \left\{ -\frac{48\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(-m^4 + m^2 + \Pi_2^2 - 1)\text{ds}^2(\zeta, m)}{(2m^2 - 1 - \Pi_2)\text{ds}^2(\zeta, m) - 3m^2(1 - m^2)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (69)$$

under the same constraint (48).

Family-X. Applying the parameters $\chi_0 = \frac{1 - m^2}{4}, \chi_2 = \frac{1 + m^2}{2}$, and $\chi_4 = \frac{1 - m^2}{4}$, we get $\eta(\zeta) = \text{nc}(\zeta, m) \pm \text{sc}(\zeta, m)$ or $\eta(\zeta) = \frac{\text{cn}(\zeta, m)}{1 \pm \text{sn}(\zeta, m)}$, and we maintain that

$$\Psi(x, t) = \left\{ \frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(m^4 + 14m^2 - 16\Pi_2^2 + 1)[\text{nc}(\zeta, m) \pm \text{sc}(\zeta, m)]^2}{2(1 + m^2 - 2\Pi_2)[\text{nc}(\zeta, m) \pm \text{sc}(\zeta, m)]^2 + 3(1 - m^2)} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (70)$$

as well

$$\Psi(x, t) = \left\{ \frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(m^4 + 14m^2 - 16\Pi_2^2 + 1)\text{cn}^2(\zeta, m)}{2(1 + m^2 - 2\Pi_2)\text{cn}^2(\zeta, m) + 3(1 - m^2)[1 \pm \text{sn}(\zeta, m)]^2} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (71)$$

Fig. 1. Profile of a stochastic wave-type soliton corresponding to solution (19).

underneath the bounds of this limitation

$$8\Pi_4^2(1+m^2-2\Pi_2)\left[9(1-m^2)^2-8(1+m^2-2\Pi_2)(1+m^2+\Pi_2)\right] + 3\Pi_6\left[3(1-m^2)^2-4(1+m^2)^2+16\Pi_2^2\right]^2 = 0. \quad (72)$$

For m near 0^+ there exist periodic solutions

$$\Psi(x, t) = \left\{ \frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{(1-16\Pi_2^2)[\sec(\zeta) \pm \tan(\zeta)]^2}{3+2(1-2\Pi_2)[\sec(\zeta) \pm \tan(\zeta)]^{22}} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (73)$$

additionally

$$\Psi(x, t) = \left\{ \frac{12\mu^4 c_4^2}{(8\mu^2 c_2 c_4 - 3L_1 c_3)} \left[\frac{1-16\Pi_2^2}{2(1-2\Pi_2)+3[\sec(\zeta) \pm \tan(\zeta)]^2} \right] \right\}^{\frac{1}{2}} e^{i[-\kappa x + \omega t + \sigma W(t) - \sigma^2 t]}, \quad (74)$$

that is, subject to the restriction:

$$8\Pi_4^2(1-2\Pi_2) + 3\Pi_6(1-4\Pi_2)^2 = 0, \quad \Pi_2 \neq \pm \frac{1}{4}. \quad (75)$$

4. Numerical simulations

The graphs illustrated herein represent multiple solutions to Eq. (1). The analysis of the subsequent data may elucidate specific conclusions derived from our study. The initial reference points are determined by choosing a limited subset of the defined parameter range.

Fig. 1 shows 3D graphical models of the stochastic wave-type (bright soliton) soliton corresponding to solution (19), which were made using the values $\mu = 0.5, \kappa = 0.5, A = 2, \beta = -(1 + \sigma^2)$, and the rest of the parameters $a = b = c_1 = c_2 = c_3 = c_4 = \omega = 1$, as well as $W(t) = \cosh(2t)$. The graph shows the values of σ that are indicated in the legend.

Fig. 2 depicts a three-dimensional graphical representation of the stochastic (dark) wave soliton (Eq. (38)) utilizing $\kappa = -0.5, \omega = c_2 =$

$c_3 = -1, \beta = -0.67(1 + \sigma^2)$, and all remaining parameters set to unity. Here we take $W(t) = 3-t$. Consult the legend for the σ parameter utilized in our calculations.

Fig. 3 demonstrates a 3D graphical representation of the stochastic wave singular-type soliton associated with solution (52) with $\kappa = \mu = 0.5, \beta = -(1 + \sigma^2)$, and the remaining parameters equal to 1, with $W(t) = \sinh(t^2)$. Please refer to the legend for the σ parameter that was employed in our calculations.

Fig. 4: Under appropriate conditions, a computer simulation of the stochastic Jacobi-elliptic wave solution (58) was executed in three dimensions with parameters $\omega = b = \mu = -1, m = 1/\sqrt{3}, \beta = 1 - 0.5\sigma^2$, and the other parameters normalized to 1, with $W(t) = 5t + 3$. The accompanying legend illustrates the parameter value of σ employed in our computational analyses.

Fig. 5: Under appropriate conditions, a three-dimensional computer model of the stochastic wave periodic solution corresponding to Eq. (62) was executed with parameters $\mu = 0.5, \kappa = -0.5, \beta = 0.33(1 - \sigma^2)$, with all other parameters equal to 1 and $W(t) = 5t + 3$. The accompanying legend illustrates the parameter value of σ employed in our computational analyses.

5. Physical interpretation

The findings yield important physical insights into soliton dynamics within the stochastic resonant nonlinear Schrödinger equation characterized by cubic, quintic, and septic nonlocal nonlinearities. Solitons manifest as stable localized waveforms in deterministic regimes, resulting from the equilibrium between dispersion and nonlinear self-focusing effects. The introduction of multiplicative noise alters this balance, resulting in amplitude modulations, phase shifts, and the emergence of new soliton families. Stochastic contributions represent realistic conditions in optical fibers, photonic systems, and plasma waves, where fluctuations from thermal noise, spontaneous emission, or environmental perturbations are inevitable.

The bright soliton solutions (Fig. 1) illustrate the stability of localized pulses amid cubic–quintic–septic nonlinearities and nonlocal effects. The higher-order terms inhibit collapse, whereas the nonlocal

Fig. 2. Profile of a stochastic wave soliton (Eq. (38)).

Fig. 3. Profile of a stochastic wave singular-type soliton associated with solution (52).

contribution disperses nonlinear interactions over a finite area, thereby improving stability. This denotes stable optical pulses in nonlinear fibers or photonic lattices, where randomness exists without compromising coherence.

The dark soliton solutions (Fig. 2) exhibit localized depressions within a continuous background. These occur when defocusing nonlinear contributions prevail. Stochastic perturbations cause fluctuations in soliton depth and width, suggesting that noise may destabilize or broaden the background. These dynamics are especially significant in

plasma physics and defocusing optical media, where environmental noise influences nonlinear wave propagation.

The singular soliton solutions (Fig. 3) demonstrate significant localization characterized by distinct amplitude features. Stochastic perturbations enhance these structures, resulting in rogue-wave-like behavior or intensity spikes. This underscores the dual function of noise: it can disrupt smooth soliton propagation while simultaneously generating novel extreme waveforms, which may have applications in nonlinear optics and high-intensity pulse dynamics.

Fig. 4. Profile of a stochastic Jacobi-elliptic wave solution (58).

Fig. 5. Profile of the stochastic periodic-wave solution (62).

The Jacobi elliptic solutions (Fig. 4) illustrate periodic wave trains that transition smoothly between solitary and periodic states, contingent upon the elliptic modulus. Noise alters periodic backgrounds through the induction of amplitude modulation and phase jitter. These behaviors are associated with optical pulse trains in photonic lattices or nonlinear resonators, where stochastic resonance may enhance coherence or foster irregularity.

The periodic solutions illustrated in Fig. 5 exhibit soliton-like structures that recur periodically in response to stochastic forcing. These

solutions connect isolated solitons with continuous periodic waves. Noise serves as a driving mechanism that facilitates transitions between solitary and periodic states, which is essential for comprehending pulse shaping and ensuring robust signal transmission in optical communication systems.

The interplay of higher-order nonlinearities, nonlocal interactions, and stochastic perturbations enhances the dynamics of soliton solutions. The data demonstrate that noise is not inherently harmful; rather, it can stabilize, modulate, or even create new soliton families via stochastic

Table 1
Dominant effects in different soliton families.

Solution (Eq.)	Dominant nonlinearity	Dominant stochastic effect	Key feature	Physical regime
(19)	Cubic + nonlocal	Moderate noise-induced phase diffusion	Stable localized pulse	Focusing media with weak noise
(38)	Quintic/septic defocusing	Noise-induced background fluctuations	Localized depression	Defocusing fibers with thermal noise
(52)	Septic + resonant term	Enhanced extreme events (rogue waves)	High-intensity spikes	High-power pulses with turbulence
(58)	Combined cubic–quintic–septic	Periodic amplitude modulation	Wave trains with elliptic periodicity	Periodic structures in photonic lattices
(62)	Nonlocal + resonant	Stochastic resonance (noise-enhanced periodicity)	Periodic recurrences	Signal amplification in noisy channels
(18)	Cubic–septic balance	Multiplicative noise stabilization	Hybrid pulse profile	Media with competing nonlinearities
(48)	Septic self-focusing	Noise-controlled collapse suppression	Collapse-arrested pulses	High-intensity beam propagation
(55)	Nonlocal defocusing	Noise-induced phase jitter	Asymmetric singular profiles	Nonlocal media with fluctuations
(60)	Higher-order dispersion	Stochastic pattern formation	Complex interference patterns	Metamaterials with disorder
(73)	Resonant + IMD	Transition enhancement (solitary ↔ periodic)	Breather-like dynamics	Active dispersion-managed systems

resonance. This research enhances theoretical comprehension and offers practical guidance for designing optical and photonic devices in noisy environments (Table 1).

Key Patterns:

- (1) **Bright solitons** emerge when cubic focusing balances dispersion, with noise mainly affecting the phase.
- (2) **Dark/singular solitons** require higher-order (quintic/septic) defocusing, where noise modulates the background stability.
- (3) **Elliptic/periodic families** thrive under combined nonlinearities where noise induces transitions between solution types.
- (5) **Stochastic resonance** is prominent in periodic solutions where noise constructively enhances signal coherence.
- (6) **Nonlocal terms** generally stabilize solutions against noise-induced collapse but spread nonlinear interactions spatially.

This table reveals that specific nonlinear terms must dominate to produce each soliton type, while stochastic effects selectively amplify or modify certain features (phase, amplitude, stability). The cubic term typically drives bright solitons, septic terms enable extreme events, and nonlocal/resonant terms support structured patterns. Noise acts as a control parameter that can either disrupt or enhance these inherent nonlinear behaviors depending on its intensity and correlation with system parameters.

6. Discussion and conclusions

This paper investigated the stochastic resonant nonlinear Schrödinger equation (NLSE) that incorporates cubic-quintic-septic nonlinearities, nonlocal effects, intermodal dispersion (IMD), and multiplicative noise within the Itô framework. Kudryashov's algorithm and the P^6 -model expansion method were utilized to develop a wide range of analytical soliton solutions, encompassing bright, dark, singular, Jacobi-elliptic, and periodic families. Numerical simulations validated the analytical results, demonstrated significant alignment with the theoretical framework and highlighted the influence of higher-order nonlinearities, nonlocal interactions, and stochastic forcing on soliton behavior.

The free parameters in the model—such as dispersion coefficients (a, b), nonlocality strength c_4 , nonlinear coefficients c_1, c_2, c_3 the resonant term θ , the IMD coefficient α , and the noise intensity σ —directly determine the physical form of the soliton solutions. Variations in dispersion parameters modify the pulse width and propagation velocity, while adjusting the nonlinear coefficients controls the balance between focusing and defocusing effects, shaping whether the solution appears bright, dark, or singular. The nonlocality parameter regulates spatial smoothing and stabilizes or destabilizes wave profiles by spreading nonlinear interactions. Resonant and intermodal dispersion terms influence internal oscillations and phase evolution, altering the oscillatory

structure of Jacobi-elliptic and periodic solutions. Finally, the stochastic noise coefficient introduces amplitude fluctuations, phase diffusion, and noise-induced modulation, determining the transition between stable, resonance-enhanced, or irregular wave behaviors. Collectively, these parameters provide precise control over the amplitude, width, localization, periodicity, and stability of the obtained soliton families.

The results obtained yield several significant insights. The incorporation of cubic–quintic–septic refractive index laws enhanced the nonlinear response of the system considerably. The cubic term governed standard self-focusing dynamics, while quintic and septic contributions mitigated potential collapse, resulting in more versatile soliton families. This underscored the need for higher-order nonlinear models to accurately represent realistic photonic and plasma systems [25,26]. The role of nonlocal nonlinearities was identified as stabilizing. Nonlocal effects, achieved through the distribution of nonlinear interactions across a finite spatial domain, reduced instabilities and facilitated the persistence of coherent soliton structures despite significant perturbations [11]. This highlighted their significance in the design of robust optical systems and metamaterials. Third, stochastic perturbations served a dual function. Multiplicative noise induced amplitude modulations, phase fluctuations, and structural transitions that could destabilize solitons.

Conversely, within suitable parameter regimes, noise could enhance soliton persistence via stochastic resonance, selectively amplifying specific modes and facilitating transitions between solitary and periodic states [1–4,6,7,27]. Contemporary research underscores the constructive role of multiplicative noise in generating bifurcation structures and stochastic resonance within NLSE frameworks featuring higher-order dispersion. Nonlocal nonlinearities further stabilize these dynamics against perturbations, enabling robust soliton propagation in realistic photonic media, while detailed analyses of stochastic NLSE characteristics confirm noise-enhanced coherence in complex systems [39–41]. The constructive role of noise highlights that randomness should not be viewed solely as harmful; instead, it could serve as a mechanism for generating or stabilizing new families of nonlinear excitations. The proposed framework is limited because it relies on reducing the stochastic model into a single ODE using a travelling-wave form, which is only valid in one-dimensional conservative settings. In higher dimensions or when gain–loss terms are added, the reduction no longer holds and the model becomes non-integrable, meaning that the same closed-form analytical solutions cannot be constructed and numerical approaches would be required instead. Despite the broad range of analytical and numerical results obtained, the present study is limited by its treatment of noise as purely multiplicative white noise within the Itô framework, which may not capture colored or experimentally correlated fluctuations. Additionally, the soliton interactions, stability under long-time evolution, and higher-dimensional effects were not explored and remain open for future investigation. These limitations suggest that extending the model to more realistic noise structures and multi-dimensional

configurations would further enhance the applicability of the framework. Lastly, the different solution sets we obtained, from localized bright and dark solitons to solitary spikes and periodic trains, show how rich soliton dynamics can be when both deterministic and stochastic factors are present. The analytical frameworks employed herein can be adapted to explore higher-dimensional stochastic NLSes, gain-loss mechanisms, or systems characterized by saturable nonlinearities. These developments are pertinent to next-generation optical communication technology, plasma confinement research, and nonlinear wave manipulation in intricate media.

Future study may concentrate on expanding this paradigm to higher-dimensional models, examining the interactions of numerous stochastic solitons, and probing noise-induced transitions in dissipative or saturable systems. Experimental confirmation in photonic lattices, optical fibers, or Bose–Einstein condensates would serve as a logical extension, connecting theoretical predictions with realistic implementations.

This study advances the comprehension of stochastic soliton dynamics in nonlinear dispersive media and develops a thorough framework for examining the interactions of higher-order nonlinearities, nonlocality, and noise in generating complex wave patterns. The interaction of deterministic and stochastic effects expands the mathematical theory of NLSes and offers practical applications for contemporary optical and photonic technologies. While this study derives comprehensive soliton solutions for the stochastic resonant NLSE, analytical methods are limited to specific parameter regimes and 1 + 1 dimensions, with numerical simulations restricted to short-time behaviors where noise-induced instabilities may emerge. Higher-dimensional extensions, multi-soliton interactions, and long-term statistical analysis remain challenging due to SPDE complexity. Future work will explore experimental validation in photonic fibers, gain-loss models, and machine learning for stochastic soliton prediction.
